

PROGRAMING WITH JAVA

Arrays snacks – Credit Card Validator

semicolon

Credit card numbers follow certain patterns: it must have between 13 and 16 digits, and the number must start with:

4 for Visa Cards

5 for MasterCard ,

37 for American Express Cards

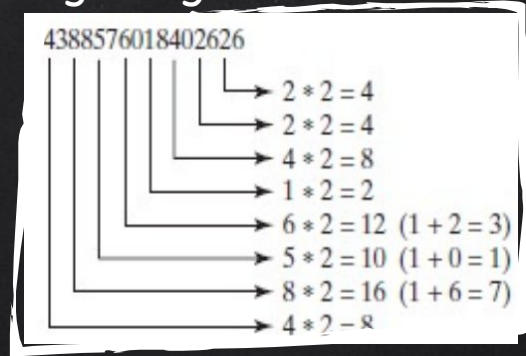

6 for Discover cards.

In 1954, Hans Luhn of IBM proposed an algorithm for validating credit card numbers. The algorithm is useful to determine whether a card number is entered correctly. Credit card numbers are generated following this validity check, commonly known as the Luhn check or the Mod 10 check, which can be described as follows:

Consider the credit number – **4388576018402626**

1. Double every second digit from right to left. If doubling of the digit results in a two-digit number, add up the two digits to get a single-digit number.

2. Now add all single-digit numbers from Step 1:

$$4 + 4 + 8 + 2 + 3 + 1 + 7 + 8 = 37$$

3. Add all digits in the odd places from right to left in the card number.

$$6 + 6 + 0 + 8 + 0 + 7 + 8 + 3 = 38$$

4. Sum the results from Steps 2 and 3:

$$37 + 38 = 75$$

5. If the result from Step 4 is divisible by 10, the card number is valid; otherwise, it is invalid. For example, the number 4388576018402626 is **invalid**, but the number 4388576018410707 is **valid**

– Implement an application that requests for a credit card number and returns the credit card type and validity status.
